### A

Page: [Argument injection](#)

Argument injection is a type of attack based on tampering with input parameters of a page. This can enable attackers to see data which they normally cannot see or to modify data which they normally cannot modify, via the user interface. Example of argumen

Page: [Autocomplete deactivation](#)

Autocomplete is a feature, which remembers submitted user names in login forms and also all words submitted through any forms in the system. In this topic though, we will focus only on the autocomplete functionality in login forms: image2013-7-29 8:32:27.

Page: [Avoiding security vulnerabilities in code](#)

In this section you will learn how to protect your system against various types of hacker and scripting attacks. @self

Page: [Banned IPs](#)

IP banning prevents users with specified IP addresses from using your website. Kentico CMS provides these levels of IP address banning: Access to the website - users with the specified IP address cannot access the site at all. Login - users cannot log in

**C**

Page: [Clickjacking](#)

Clickjacking is a type of attack where the attacker tricks website users into clicking something different than what they see, thus performing an action that may, for example, reveal confidential data or have any other negative impact on the user. In a ty

Page: [Command injection](#)

Code injection in ASP.NET is not a well known issue. It is because in ASP.NET, code files are not inserted one into another dynamically (like in PHP). Programmers can only register controls in the web.config file or on a page. But dynamic code injection i

Page: [Configuring e-mail confirmations](#)

It is recommended to use all kinds of e-mail confirmations Kentico provides. The e-mail confirmations protect the users from being subscribed to mass e-mails or having their passwords changed without their knowledge. Password change confirmation You can a

Page: [Configuring permissions securely](#)

Permissions allow you to control access to the particular sections of the Kentico administration interface by users. To learn how the whole system works, continue through the following sections: Configuring permissions securely Configuring permissions sec

Page: [Configuring SSL](#)

The Secure Sockets Layer protocol is used to encrypt Internet communication. This is important for protecting privacy of your users and for safekeeping sensitive information that is being sent. If you do not protect the sensitive information on your websi

Page: [Creating custom error handling pages](#)

You can configure the system to display custom pages instead of standard error messages. Custom pages help reduce the inconvenience caused to visitors if they run into an error while browsing your website, and also improves the security of the site by hid

Page: [Cross site request forgery \(CSRF/XSRF\)](#)

A browser typically uses two ways of requesting web applications. It sends data via URL parameters where HTTP GET request is used and sends data via forms where HTTP POST is used. The application typically does some action, for example, inserts a new user

Page: [Cross site scripting \(XSS\)](#)

Cross site scripting happens when somebody (an attacker) inserts a malicious input into a form (for example, a piece of HTML code). Depending on what happens after that, we divide XSS attacks into these types: Persistent XSS - a web application (like an
